ON THE EXPRESSION OF A FUNCTION THROUGH ITS INTEGRALS OVER ELLIPSOIDS

(Presented by Academician I. G. Petrovskii, May 22, 1965)

Let

$$P = P(x) = \sum_{s,t=1}^n a_{st} x_s x_t$$

be a positive definite quadratic form in Euclidean space of odd dimension n , and let $\delta^{(p)}(c^2 - P)$ be a functional on the space K of finite infinitely differentiable functions. To a function $f(x)$ from K we associate its integrals over ellipsoids

$$\tilde{f}_p(x) = \int f(x+y) \delta^{(p)}(c^2 - P(y)) dy$$

for fixed p , where $dy = dy_1 \dots dy_n$; the integration is carried out over all values of the variables (which is also understood for the other integrals). It is required, knowing $\tilde{f}_p(x)$, to reconstruct the function $f(x)$.

The following results are obtained in the paper:

1. If $f(x)$ is concentrated inside the domain $P(x) \leq c^2$, then

$$f(x) = (-1)^{(p-q)/2} \frac{2c^2 \Delta}{\pi^{n-1}} \int \tilde{f}_p(x+y) \delta^{(q)}(c^2 - P(y)) dy, \quad (1)$$

where $\Delta = \det \|a_{st}\|$; q is determined from the condition $p+q = n-1$ (this equality is assumed to hold also below); $p = 0, 1, \dots, n-1$, and also

$$f(x) = -(-1)^{(p-q)/2} \frac{\Delta}{2\pi^{n-1}} \int L_p \tilde{f}_{p-1}(x+y) \delta^{(q-1)}(c^2 - P(y)) dy, \quad (2)$$

where

$$L_p = \sum_{s,t=1}^n a^{st} \frac{\partial^2}{\partial x_s \partial x_t};$$

a^{st} are the coefficients of the matrix inverse to $\|a_{st}\|$; $p = 1, 2, \dots, n-2$.

2. If $\check{f}_p(x)$ and $\check{f}_{p-1}(x)$ are known, then

$$f(x) = \frac{(-1)^{(p-q)/2} \Delta}{4\pi^{n-1}} \left[4c^2 \int \check{f}_p(x+y) \delta^{(q)}(c^2 - P(y)) dy - \int L_p \check{f}_{p-1}(x+y) \delta^{(q-1)}(c^2 - P(y)) dy \right],$$

where $f(x)$ is an arbitrary function from K , $p = 1, 2, \dots, n-2$.

This establishes the equivalence of (1) and (2) for those values of p for which (2) is defined.

3. For an arbitrary function from K ,

$$f(x) = \frac{2\Delta c^2}{\pi^{n-1}} \sum_{k=0}^{\infty} (-1)^k (2k+1) \int \check{f}_{(n-1)/2}(x+y) \delta^{((n-1)/2)}(c^2(2k+1)^2 - P(y)) dy,$$

$$f(x) = -\frac{\Delta}{2\pi^{n-1}} \sum_{k=0}^{\infty} \int L_P \check{f}_{(n-3)/2}(x+y) \delta^{((n-3)/2)}(c^2(2k+1)^2 - P(y)) dy, \quad (3)$$

where the sums terminate for sufficiently large k .

Relation (1) for $p = 0$ in the case when P is a sum of squares was obtained earlier by another method by N. Ya. Vilenkin. For $n = 3$, (3) is John's formula for expressing a function through its spherical means over spheres of fixed radius in an affinely invariant notation ((¹), p. 109).

We next prove some relations for delta-functions, from which these results follow directly.

Denote by

$$Q = Q(\sigma) = \sum_{s,t=1}^n a^{st} \sigma_s \sigma_t$$

the quadratic form conjugate to P . As is known from (²), the following formulas hold:

$$F[\delta^{(p-1)}(c^2 - P)] = \frac{\pi^{n/2}}{\sqrt{\Delta}} \left(\frac{2c}{Q^{1/2}} \right)^{n/2-p} J_{n/2-p}(cQ^{1/2}), \quad (4)$$

$$F[L_P \delta(x)] = -Q, \quad (5)$$

where F denotes the Fourier transform; $p \geq 1$ is an integer; $c > 0$, $\delta(x) = \delta(x_1, \dots, x_n)$ is the delta-function; $J_{n/2-p}$ is a Bessel function. The left-hand sides of (4) and (5) are understood as functionals on the space Z , dual to K with respect to the Fourier transform.

Consider the generalized function $\delta^{(p)}(c^2 - P) * \delta^{(q)}(c^2 - P)$, defined by means of convolution. Since the inverse Fourier transform F^{-1} of the function 1 is $\delta(x)$, using the properties of the Fourier transform of a convolution (see ⁽³⁾) and (4), and introducing the notation $z = cQ^{1/2}$, $m = (p - q)/2$ (m an integer), we shall have

$$\delta(x) = (-1)^m \frac{2c^2 \Delta}{\pi^{n-1}} \delta^{(p)}(c^2 - P) * \delta^{(q)}(c^2 - P) + A_m(c, P), \quad (6)$$

where

$$A_m(c, P) = F^{-1} \left[1 - (-1)^m \pi z J_{-m-1/2}(z) J_{m-1/2}(z) \right], \quad p = 0, 1, \dots, n-1.$$

Similarly, taking into account (5), the differentiation rule for convolution, and the equality

$$J_\nu(z) J_{-\nu+1}(z) + J_{-\nu}(z) J_{\nu-1}(z) = \frac{2 \sin \nu \pi}{\pi z},$$

one can obtain

$$\delta(x) = -(-1)^m \frac{\Delta}{2\pi^{n-1}} \delta^{(p-1)}(c^2 - P) * L_P \delta^{(q-1)}(c^2 - P) - A_m(c, P).$$

We shall show that the functional $A_m(c, P)$ is concentrated outside the domain $P(x) < (2c)^2$.

For the proof, using the representation of Bessel functions with half-integral index in terms of Lommel polynomials $R_{m,\nu}(z)$ (⁽⁴⁾, p. 326), we transform the expression for $A_m(c, P)$:

$$F[A_m] = U_m(z) \cos 2z + V_m(z) \sin 2z,$$

where

$$U_m(z) = R_{m-1,3/2}(z)R_{m-1,1/2}(z) + R_{m,1/2}(z)R_{m-2,3/2}(z),$$

$$V_m(z) = R_{m-1,3/2}(z)R_{m-2,3/2}(z) - R_{m,1/2}(z)R_{m-1,1/2}(z).$$

Here we have used Krell's formula for Lommel polynomials ((⁴), p. 328). The functions $U_m(z)$ and $V_m(z)$ are polynomials in negative powers of z , and the validity of the assertion follows from the following lemma.

Lemma. The functional $F^{-1}[\cos z/z^{2k}]$ for integer $k < n/2$ and the functional $F^{-1}[\sin z/z^{2k+1}]$ for integer $k < (n-1)/2$ are concentrated outside the domain $P(x) < c^2$.

For the proof of the lemma it suffices, using formulas 8.411,7; 6.699,1 and 2 from (⁵), to establish two relations with a hypergeometric function. We give one of them:

$$z^{\lambda-n} \cos z e^{-i(x,\sigma)} d\sigma = \frac{2\sqrt{\Delta}\pi^{n/2}}{c^n \Gamma(n/2)} \Gamma(\lambda) \cos \frac{\pi\lambda}{2} F\left(\frac{\lambda}{2}, \frac{\lambda+1}{2}, \frac{n}{2}; \frac{P}{c^2}\right).$$

Here λ is a complex parameter, $d\sigma = d\sigma_1 \dots d\sigma_n$, $P(x) < c^2$. For $0 < \operatorname{Re} \lambda < (n+1)/2$ the integral converges directly; for other values of $\operatorname{Re} \lambda$ it is understood in the regularized sense, by virtue of the uniqueness of analytic continuation.

Let k be an integer. For the case $m = 0$, analogously to (6), we have

$$\begin{aligned} F[2\Delta c^2 \delta^{((n-1)/2)}(c^2 - P) * \delta^{((n-1)/2)}(c^2(2k+1)^2 - P)] = \\ = \pi^{n-1}(\cos 2kz + \cos 2(k+1)z), \end{aligned}$$

and further

$$\begin{aligned} \delta(x) = \frac{2\Delta c^2}{\pi^{n-1}} \delta^{((n-1)/2)}(c^2 - P) * \\ * \sum_{k=0}^{r-1} (-1)^k (2k+1) \delta^{((n-1)/2)}(c^2(2k+1)^2 - P) + (-1)^r B_n(cr, P), \end{aligned}$$

where $r \geq 1$ is an arbitrary integer,

$$B_n(c, P) = \frac{2c\sqrt{\Delta}}{\pi^{(n-1)/2}} \delta^{((n-1)/2)}(4c^2 - P).$$

In the same way one easily obtains

$$\delta(x) = -\frac{\Delta}{2\pi^{n-1}} \delta^{((n-3)/2)}(c^2 - P) * L_P \sum_{k=0}^{r-1} \delta^{((n-3)/2)}(c^2(2k+1)^2 - P) + B_n(cr, P).$$

In conclusion I express my gratitude to M. I. Graev and N. Ya. Vilenkin for discussion and useful advice.
