I. A. BAKHTIN

APPLICATION OF TOPOLOGICAL METHODS TO THE STUDY OF THE CRITICAL REGIME OF A REACTOR

(Presented by Academician I. N. Vekua on 24 V 1965)

In the present work, by the topological methods of the monograph of M. A. Krasnosel'skii ⁽¹⁾, a special system of equations of the form

$$\begin{aligned} x &= \mu A(x, y), \\ y &= B(x, y). \end{aligned} \tag{1}$$

is investigated.

The results obtained are applied to the study of the critical regime of a reactor.

1. We introduce some notation which we shall use. Let E_1 and E_2 be two real Banach spaces with cones K_1 and K_2 ⁽²⁾. Denote by $E = E_1 \times E_2$ the Banach space of elements $z = (x, y)$ ($x \in E_1$, $y \in E_2$) with norm $\|z\| = \|x\| + \|y\|$. Obviously, $K = K_1 \times K_2$ is a cone in the space E .

Let A and B be operators acting respectively from the space E into E_1 and E_2 . Then the operator $C = (A, B)$ will act in the space E . Denote by $C(\mu)$ the operator $(\mu A, B)$. It is easy to see that system (1) can be written in the form of a single equation

$$z = C(\mu)z. \tag{2}$$

By P and Q we denote the Fréchet derivatives at zero θ (if they exist) of the operators A and B . By D and $D(\mu)$ we denote respectively the operators (P, Q) and $(\mu P, Q)$. Obviously, the operator $D(\mu)$ is the Fréchet derivative at zero θ of the operator $C(\mu)$. By Q_1 and Q_2 we denote the operator Q respectively on the subspaces E_1 and E_2 .

2. In this item we shall formulate two theorems on the computation of rotations of vector fields, analogous to the theorems of Leray and Schauder ⁽¹⁾.

A solution $z = (x, y)$ of equation (2) will be called a **semiproper vector** of the operator C , if $x \neq \theta$. The corresponding number μ ($\lambda = 1/\mu$) will be called a **semicharacteristic (semiproper) number** of the operator C . The totality of all semiproper numbers of the operator C will be called the **semispectrum of the operator C** . The multiplicity of the characteristic number μ of the operator

$$P_0x = P[x, (I - Q_2)^{-1}Q_1x]$$

will be called the **π -multiplicity** of the semicharacteristic number μ of the linear operator D .

Let $(T_1)_{r_1} \subset E_1$ be the ball $\|x\| \leq r_1$, and $(T_2)_{r_2} \subset E_2$ the ball $\|y\| \leq r_2$. Denote by $(S_1)_{r_1}$ and $(S_2)_{r_2}$, respectively, the spheres $\|x\| = r_1$ and $\|y\| = r_2$.

Theorem 1. *Let the linear operator $D = (P, Q)$ be completely continuous. Let unity not be a point of the spectrum of the operator Q_2 . Then the rotation γ of the vector field $z - D(\mu_0)z$ ($\mu_0 \neq 0$) ⁽¹⁾ on the boundary Γ of the set $(T_1)_{r_1} \times (T_2)_{r_2}$ is equal to the product of the rotations γ_1 and γ_2 of the vector fields $x - \mu_0 P[x, (I - Q_2)^{-1}Q_1x]$ and $y - Q_2y$, respectively, on the spheres*

$(S_1)_{r_1}$ and $(S_2)_{r_2}$, i.e. $\gamma = (-1)^\beta \gamma_2$, where β is the sum of the π -multiplicities of all semi-characteristic numbers $\mu \in (0, \mu_0)$ of the operator D .

Theorem 2. Let zero θ be a fixed point of the completely continuous vector field $\Phi = I - C(\mu_0)$ ($\mu_0 \neq 0$) ⁽¹⁾. Let D be the Fréchet derivative of the operator C at zero θ . Finally, suppose that unity is not an eigenvalue of either the operator $D(\mu_0)$ or Q_2 .

Then θ is an ⁽¹⁾ isolated fixed point of the vector field Φ , and the index ⁽¹⁾ of this point is equal to $(-1)^\beta \gamma_2$, where β is the sum of the π -multiplicities of all semi-characteristic numbers of the operator D from the interval $(0, \mu_0)$, and γ_2 is the index of zero θ of the field $I - Q_2$ in E_2 .

3. We now present a theorem on bifurcation points of operators. We shall call the number μ_0 a point of π -bifurcation of the operator C if, for every $\varepsilon > 0$, there exists a semi-characteristic number μ of the operator C such that $|\mu - \mu_0| < \varepsilon$ and to the number μ there corresponds at least one semi-eigenvector $z : C(\mu)z = z$, with norm $\|z\| < \varepsilon$.

Theorem 3. Let the completely continuous operator C ($C\theta = \theta$) have at zero θ the Fréchet derivative D . Suppose that unity is not a point of the spectrum of the operator Q_2 .

Then:

- 1) Only semi-characteristic numbers of the operator D and the number zero can be points of π -bifurcation of the operator C .

- 2) Every semi-characteristic number μ_0 of odd π -multiplicity of the operator D is a point of π -bifurcation of the operator C ; moreover, at this point there corresponds a continuous branch ⁽¹⁾ of semi-eigenvectors of the operator C . If it is additionally known that zero θ is an isolated fixed point of the vector field $I - C(\mu_0)$, then the semispectrum of the operator C includes some interval.
4. In the present section we formulate a theorem that is an analogue of the topological principle of M. A. Krasnosel'skii (see ⁽¹⁾, pp. 244-249, Theorem 1.1).

Theorem 4. Let the positive operator $C = (A, B)$ ($CK \subset K$) be completely continuous. Suppose that

$$\inf_{x \in \Gamma_1 \cap K_1, y \in K_2 \cap (T_2)_{r_2}} \|A(x, y)\| > 0,$$

where Γ_1 is the boundary of some open set $G_1 \subset E_1$ containing zero θ . Finally, suppose that for any $x \in \Gamma_1 \cap K_1$ the operator $B_{xy} = B(x, y)$ maps the convex set $K_2 \cap (T_2)_{r_2}$ into itself.

Then the operator C has a semi-eigenvector $z = (x, y)$ in the cone K , with $x \in \Gamma_1 \cap K_1$, $y \in K_2 \cap (T_2)_{r_2}$.

5. We now turn to the application of the results obtained. Let the distribution of the neutron flux Φ and of the temperature T over the volume V of the reactor be described by the ⁽³⁾ equations

$$\begin{aligned} \nabla^2 \Phi + \mu a(T) \Phi &= 0, & \Phi|_{\Sigma} &= 0; \\ \nabla^2 T + b(T) \Phi &= 0, & T|_{\Sigma} &= T_0, \end{aligned} \quad (3)$$

where Σ is the boundary of the reactor, assumed to be sufficiently smooth and convex. In view of the physical meaning ⁽³⁾, the coefficients $a(T)$ and $b(T)$ are positive and continuous. The system (3) of differential equations can be replaced by the equivalent system of integral equations

$$\begin{aligned} \Phi(P) &= \mu \int_V K(P, Q) a[T(Q) + T_0] \Phi(Q) dQ = \mu A(\Phi, T), \\ T(P) &= \int_V K(P, Q) b[T(Q) + T_0] \Phi(Q) dQ = B(\Phi, T). \end{aligned} \quad (4)$$

The system (4) was studied by O. B. Moskalev in paper (3). We investigate it under other restrictions.

Below, the roles of E_1, E_2 and K_1, K_2 are played respectively by the space $C(V)$ of functions continuous on V and the cone $K(V)$ of nonnegative functions of the space $C(V)$.

In paper (3) it is shown that the operator $C = (A, B)$ is positive and completely continuous.

Theorem 5. The points of π -bifurcation of the system (4) can only be the characteristic numbers of the operator

$$A_0\Phi = a(T_0) \int_V K(P, Q)\Phi(Q) dQ.$$

Each characteristic number of odd multiplicity of the operator A_0 is a point of π -bifurcation of the system (4). In particular, the characteristic number μ_0 of the operator A_0 , to which there corresponds the eigenvector $\Phi_0 \in K_1$, is a point of π -bifurcation of the system (4).

If, in addition, it is known that the kernel $K(P, Q)$ of the system (4) is symmetric and that in some neighborhood of the point $T = 0$ the functions $a(T + T_0)$ and $b(T + T_0)$ have continuous derivatives respectively up to orders n and m inclusive, where

$$a'(T_0) = \dots = a^{(n-1)}(T_0) = 0, \quad a^{(n)}(T_0) \neq 0$$

and

$$b'(T_0) = \dots = b^{(m-1)}(T_0) = 0, \quad b^{(m)}(T_0) \neq 0,$$

then for any characteristic number μ_* of odd multiplicity of the operator A_0 :

- a) if n is an even number and $a^{(n)}(T_0) < 0$, then the half-spectrum of the system (4) completely fills some interval $(1/\mu_1, 1/\mu_*)$, where $\mu_1 < \mu_*$ if $\mu_* < 0$, and $\mu_2 < \mu_*$ if $\mu_* > 0$.
- b) if n is an even number and $a^{(n)}(T_0) > 0$, then the half-spectrum of the system (4) completely fills some interval $(1/\mu_2, 1/\mu_*)$, where $\mu_2 > \mu_*$ if $\mu_* < 0$, and $\mu_2 < \mu_*$ if $\mu_* > 0$.

Definition. We shall say that the semi-eigenvectors z of the operator C form a conditionally continuous branch of infinite length if, for the boundary Γ_1 of any bounded open set $G_1 \subset E_1$ containing zero θ , there exists such a semi-eigenvector $z = (x, y)$ of the operator C that $x \in \Gamma_1$.

Theorem 6. Suppose that for all $T \geq 0$

$$b(T + T_0) \leq \alpha + \beta T^q,$$

where $\alpha, \beta > 0$, $q \in (0, 1)$.

Then the semi-eigenvectors $z = (\Phi, T) \in K$ of the system (4) form a conditionally continuous branch of infinite length.

If, in addition, it is known that:

a) there exists the limit

$$\lim_{T \rightarrow \infty} a(T + T_0) = a_0 < \infty;$$

b) for all $T \geq 0$

$$b(T + T_0) \geq b_0 > 0,$$

then the half-spectrum of the system (4) includes the interval

$$\left(\frac{1}{\mu_0}, \frac{1}{\mu_0} \frac{a_0}{a(T_0)} \right).$$

In conclusion, the author expresses sincere gratitude to M. A. Krasnosel'skii for his attention to the work.
