V. G. VIZING

ON THE NUMBER OF EDGES IN A GRAPH WITH GIVEN RADIUS

(Presented by Academician A. D. Aleksandrov on 20 VI 1966)

In this note the maximum number of edges in an n -vertex graph having a given radius is established. Only finite connected undirected graphs without loops and parallel edges are considered ⁽¹⁾.

The **distance** $\rho(x, y)$ between vertices x and y is the length (the number of edges) of the shortest chain joining x and y . The **radius** $r(G)$ of a graph G is the greatest integer possessing the following property: whatever vertex x of the graph G is taken, there is a vertex y such that $\rho(x, y) \leq r(G)$. The **diameter** $d(G)$ of a graph G is the greatest distance between two vertices of the graph G .

Obviously, $r(G) \leq d(G)$. If G is a tree, then

$$r(G) = \lfloor (d(G) + 1)/2 \rfloor.$$

It follows from this, in particular, that the number of vertices in a graph is at least twice its radius.

We shall denote by $\sigma(x)$ the degree of the vertex x , and by $\sigma(G)$ the maximum degree of a vertex of the graph G .

Lemma 1. In an n -vertex graph G ,

$$\sigma(G) \leq n - 2r(G) + 2.$$

Lemma 2. Let G be an n -vertex graph with $r(G) \geq 3$, and let x and y be vertices of G with $\rho(x, y) \geq 3$. Then

$$\sigma(x) + \sigma(y) \leq n - 2r(G) + 4.$$

The proofs of Lemmas 1 and 2 are analogous.

We prove Lemma 2. Let the vertices $x_1, x_2, \dots, x_i$ be adjacent to the vertex x , and the vertices $y_1, y_2, \dots, y_j$ to the vertex y . Construct a tree T covering the graph G and containing the edges

$$(x, x_1), \dots, (x, x_i), (y, y_1), \dots, (y, y_j).$$

It must be that

$$d(T) \geq 2r(G) - 1.$$

Take an elementary chain joining two most distant vertices of the tree T . This chain contains no more than 6 vertices from the set

$$x, x_1, \dots, x_i; y, y_1, \dots, y_j$$

and no fewer than $2r(G) - 6$ other vertices. Consequently,

$$n \geq 2r(G) - 6 + i + 1 + j + 1,$$

whence

$$\sigma(x) + \sigma(y) = i + j \leq n - 2r(G) + 4,$$

as was required to prove.

Let n and k be natural numbers and let $n \geq 2k \geq 2$. Denote by $f(n, k)$ the maximum number of edges that an n -vertex graph with radius k may have, and by $C(n, k)$ an n -vertex graph with $f(n, k)$ edges and with $r(C(n, k)) = k$. Obviously,

$$f(n + 1, k) > f(n, k)$$

and

$$f(n, k + 1) < f(n, k).$$

Theorem.

$$f(n, 1) = \frac{n(n-1)}{2}, \quad f(n, 2) = \left\lfloor \frac{n(n-2)}{2} \right\rfloor;$$

for $k \geq 3$,

$$f(n, k) = \frac{n^2 - 4kn + 5n + 4k^2 - 6k}{2}.$$

Proof. The first two equalities are obvious. Now let $k \geq 3$. For brevity denote

$$g(n, k) = \frac{n^2 - 4kn + 5n + 4k^2 - 6k}{2} \quad (n \geq 2k \geq 6).$$

We first show that $f(n, k) \geq g(n, k)$. Indeed, let the graph H have the following structure: its vertices are

$$a_1, a_2, \dots, a_{2k}, b_1, \dots, b_{n-2k};$$

the subgraph generated by the vertices $a_1, a_2, \dots, a_{2k}$ is the elementary cycle

$$[a_1, a_2, \dots, a_{2k}, a_1];$$

the vertices $b_1, \dots, b_{n-2k}$ are pairwise adjacent, and each of them is adjacent to the vertices a_1, a_2, a_3 . The n -vertex graph H has, obviously, $g(n, k)$ edges and $r(H) = k$. This proves the required inequality.

We shall prove the inequality $f(n, k) \leq g(n, k)$ by double induction on n and k .

Basis of the induction:

- 1) $f(n, 3) \leq g(n, 3)$ for every $n \geq 6$.
- 2) $f(2k, k) \leq g(2k, k)$ for every $k \geq 3$.
- 3) It is not difficult to verify that in the graph $C(n, 3)$ one can always indicate three nonintersecting pairs of vertices $\{x_1, y_1\}$, $\{x_2, y_2\}$, $\{x_3, y_3\}$ such that $\rho(x_i, y_i) \geq 3$ ($i = 1, 2, 3$). By Lemmas 1 and 2, then

$$f(n, 3) \leq \frac{[3(n-2) + (n-6)(n-4)]}{2} = \frac{(n^2 - 7n + 18)}{2} = g(n, 3).$$

- 2) This is obvious.

Induction step. Let $k \geq 4$, $n \geq 2k + 1$, and suppose it has been proved that $f(n_0, k_0) \leq g(n_0, k_0)$ if either $3 \leq k_0 < k$, or $k_0 = k$ but $n_0 < n$. Consider the subgraph L of the graph $C(n, k)$ generated by all vertices except one vertex x that is not a cut point. If $r(L) \geq k$, then, by the induction hypothesis, the graph L contains no more than $g(n-1, k)$ edges, and since, by Lemma 1, $\sigma(x) \leq n - 2k + 2$, we have $f(n, k) \leq g(n-1, k) + n - 2k + 2 = g(n, k)$.

Suppose now that any subgraph of the graph $C(n, k)$ obtained by deleting from $C(n, k)$ a vertex different from a cut point has radius $k-1$. Then for every vertex x of the graph $C(n, k)$ that is not a cut point there is a vertex y such that $\rho(y, x) = k$, but for $z \neq x$, $\rho(y, z) \leq k-1$. We shall call the vertex y conjugate to the vertex x . Obviously, if y is also not a cut point, then the vertex x is conjugate to the vertex y .

Taking into account the indicated assumption on the structure of the graph $C(n, k)$, as well as the induction hypothesis, it is not difficult to prove the validity of the inequality $f(n, k) \leq g(n, k)$ in the case where the graph has at least one cut point. Therefore we shall assume that the graph $C(n, k)$ has no cut points.

Since $d(C(n, k)) \geq k$, by Menger's theorem ⁽¹⁾, in the graph $C(n, k)$ there exists an elementary cycle of length $\geq 2k$. Among all elementary cycles of length $\geq 2k$, choose a cycle M_0 of least length $m_0 \geq 2k$. The cycle M_0 has no chords, i.e., the subgraph generated by the vertices of the cycle M_0 is an elementary cycle. Indeed, otherwise in the graph $C(n, k)$ one could indicate a set consisting of $2k-2$ vertices, the distance between any two of which does not exceed $k-1$. Since to each of these vertices there is mutually uniquely conjugate some vertex of the graph $C(n, k)$, by Lemmas 1 and 2,

$$f(n, k) \leq \frac{[(2k-2)(n-2k+4) + (n-2k+2)(n-4k+4)]}{2} < g(n, k),$$

which is impossible.

Let x be a vertex not belonging to the cycle M_0 . If a vertex of the cycle M_0 is conjugate to the vertex x , then, obviously, x is adjacent to no more than $m_0 - 2k + 3$ vertices of the cycle M_0 . If, however, a vertex y not lying on the cycle

M_0 is conjugate to the vertex x , then, having no common adjacent vertices, the vertices x and y are adjacent in total to no more than $m_0 - 2k + 6 \leq 2(m_0 - 2k + 3)$ vertices of the cycle M_0 . Thus,

$$f(n, k) \leq m_0 + (n - m_0)(m_0 - 2k + 3) + \frac{(n - m_0)(n - m_0 - 1)}{2} \leq g(n, k).$$

The theorem is proved.

Let us note in conclusion that for fixed n and k satisfying the conditions $k \geq 3$, $n \geq 2k + 2$, the graphs $C(n, k)$ need not be isomorphic.
