Yu. A. DUBINSKII

ON AN OPERATOR SCHEME AND THE SOLVABILITY OF A NUMBER OF QUASILINEAR EQUATIONS OF MECHANICS

(Presented by Academician A. Yu. Ishlinskii, 2 XII 1966)

The paper proves theorems on the solvability of a certain class of nonlinear equations in Banach spaces, making it possible to consider from a general point of view questions of the existence of solutions of quasilinear equations and systems occurring in mechanics.

§ 1. **A general scheme for stationary (elliptic) equations.** Let V, X, Y be a triple of Banach spaces; A, B nonlinear operators. The interrelation of these spaces and operators is expressed by the following diagram

$$\begin{array}{ccccc} & \xrightarrow{i} & X & \xrightarrow{A} & X^* \\ & & & & \uparrow \\ V & & & & \xrightarrow{i} V^*, \\ & & & & \downarrow \\ & \xrightarrow{i} & X & \xrightarrow{B} & Y \end{array}$$

where i is the embedding operator; V^*, X^* are the conjugate spaces.

Assume that X is separable and that the embedding $V \subset X$ is dense everywhere. Consider the equation

$$A(u) + B(u) = h, \quad (1)$$

where $u \in X$ is the unknown solution, and $h \in X^*$ is given.

Definition. A solution of equation (1) is an element $u \in X$ such that for every $v \in V$ the identity

$$\langle A(u), v \rangle + \langle B(u), v \rangle = \langle h, v \rangle \quad (2)$$

holds.

(Here $\langle w, v \rangle$ is the value of $w \in V^*$ on $v \in V$.)

Assumptions. I. Ellipticity of $A(u)$. For every $u \in V$

$$\lim_{\|u\|_X \rightarrow \infty} \frac{\langle A(u), u \rangle}{\|u\|_X} = +\infty.$$

II. Orthogonality of $B(u)$. For every $u \in V$, $\langle B(u), u \rangle = 0$.

III. The operators A and B are weakly continuous as operators from X into V^* , i.e., if $u_n \rightarrow u$ weakly in X , then $\langle A(u_n), v \rangle \rightarrow \langle A(u), v \rangle$ and $\langle B(u_n), v \rangle \rightarrow \langle B(u), v \rangle$ for every $v \in V$.

Theorem 1. *If conditions I-III are satisfied, then for every $h \in X^*$ equation (1) has at least one solution in the sense of (2).*

The proof of the theorem is carried out by B. G. Galerkin's method; here the solvability of the moment equations and the a priori estimate follow from conditions I, II, while the possibility of passage to the limit follows from condition III.

§ 2. Applications to stationary problems.

1. The Navier-Stokes system of equations. Let $G \subset \mathbb{R}^n$, $u = (u_1, \dots, u_n)$,

$$-\Delta u + \sum_{k=1}^n u_k \frac{\partial u}{\partial x_k} + \text{grad } p = h(x), \quad \text{div } u = 0, \quad u|_{\partial G} = 0. \quad (3)$$

We apply Theorem 1 to prove solvability of system (3); accordingly, set

$$X = \{u(x) \mid u(x) \in \dot{W}_2^{(1)}, \text{ div } u = 0\},$$

$$V = \{u(x) \mid u(x) \in \dot{W}_p^{(1)}, p > n, \text{ div } u = 0\}, \quad Y = L_1, \quad A(u) = -\Delta u,$$

$$B(u) = \sum_{k=1}^n u_k \frac{\partial u}{\partial x_k}.$$

Theorem 2. If $h(x) \in X^*$, then system (3) is solvable.

This result is known; see, for example, ⁽¹⁾.

Remark. It is not difficult to show that $X^* = W_2^{(-1)}/\Pi$, where Π is the subspace of potentials of the form $u(x) = \text{grad } p(x)$, $p(x) \in L_2$ (cf. ⁽¹⁾).

2. The system of large deflection of an A. Föppl plate ⁽²⁾

$$\Delta^2 \xi + b_1(\chi, \xi) = \Delta^2 \xi + \frac{\partial^2 \chi}{\partial y^2} \frac{\partial^2 \xi}{\partial x^2} - 2 \frac{\partial^2 \chi}{\partial x \partial y} \frac{\partial^2 \xi}{\partial x \partial y} + \frac{\partial^2 \chi}{\partial x^2} \frac{\partial^2 \xi}{\partial y^2} = P(x, y),$$

$$2\Delta^2 \chi + b_2(\xi) = 2\Delta^2 \chi - 2 \frac{\partial^2 \xi}{\partial x^2} \frac{\partial^2 \chi}{\partial y^2} + 2 \left(\frac{\partial^2 \xi}{\partial x \partial y} \right)^2 = 0.$$

In the domain $G \subset \mathbf{R}^2$ it is required to find a solution of the first boundary-value problem. Set

$$X = \{u = (\xi, \chi) \mid u \in \dot{W}_2^{(2)}\}, \quad Y = L_1, \quad V = \dot{W}_2^{(2)}, \quad A(u) = (\Delta^2 \xi, 2\Delta^2 \chi), \quad B(u) = (b_1(\xi, \chi), b_2(\xi)).$$

Theorem 3 (see also ^(3,4)). If $P(x, y) \in W_2^{(-2)}$, then the system of A. Föppl equations is solvable in the space $\dot{W}_2^{(2)}$.

Remark. From the smoothness theorem for the biharmonic equation it follows that if $P(x, y)$ is smooth, then the solution is also smooth.

§ 3. General scheme for nonstationary equations

Notation:

$$L_p(X) = \left\{ u(t) : [0, T] \rightarrow X \mid \|u\|^p = \int_0^T \|u\|_X^p dt < \infty \right\}, \quad 1 \leq p < \infty.$$

Consider the Cauchy problem for the equation

$$u' + A(u) + B(u) = h(t), \quad u(0) = 0, \quad (4)$$

where the operators A and B act in the following scheme:

$$\begin{array}{ccccc} & & \xrightarrow{i} & L_p(X) & \xrightarrow{A} & L_{p'}(X^*) \\ L_\infty(V) & & & & & \downarrow i \\ & & & & & L_1(V^*), \quad p' = \frac{p}{p-1}. \\ & & \xrightarrow{i} & L_p(X) & \xrightarrow{B} & Y \\ & & & & & \uparrow i \end{array}$$

Definitions:

$$F_1 = \{u(t) \mid u \in L_\infty(V), u' \in L_1(V^*), u(0) = 0\},$$

$$F_2 = \{u(t) \mid u \in L_p(X), u' \in L_1(V^*), u(0) = 0\}; \quad [w, v] = \int_0^T \langle w, v \rangle dt,$$

$$w \in L_1(V^*), \quad v \in L_\infty(V).$$

Assumptions. I. Parabolicity. $u' + A(u)$. For any function $u(t) \in F_1$,

$$\lim_{\|u\| \rightarrow \infty} \frac{[u' + A(u), u]}{\|u\|} = +\infty.$$

II. Orthogonality of $B(u)$. If $u(t) \in F_1$, then

$$[B(u), u] = 0.$$

III. The operators A and B are weakly continuous from F_2 into $L_1(V^*)$.

Theorem 4. If conditions I-III are fulfilled, then for every function $h(t) \in L_{p'}(X^*)$ there exists at least one solution $u(t) \in F_2$ of equation (4), in the sense of the identity

$$[u' + A(u) + B(u), v] = [h, v], \quad \forall v(t) \in L_\infty(V).$$

The proof is carried out by the Galerkin method with the introduction of a vanishing “viscosity” (see, for example, (5) or (6)).

§ 4. Applications to Nonstationary Problems

1. The Euler equations of motion of a rigid body in the principal axes of inertia have the form

$$I_m \frac{d\Omega_m}{dt} + (I_{m+2} - I_{m+1})\Omega_{m+1}\Omega_{m+2} = K_m(t), \quad \Omega_m(0) = 0, \quad (5)$$

where m runs through the cyclic permutation of the indices 1, 2, 3.

Put $G = \cdot$; $X = V = \mathbf{R}^3$; $A \equiv 0$; $B(\vec{\Omega}) = \{(I_{m+2} - I_{m+1})\Omega_{m+1}\Omega_{m+2}\}$, $m = 1, 2, 3$; $p = 2$. Then $L_2(X) = L_2(0, T)$, $L_1(V^*) = L_1(0, T)$; further, $F_1 = F_2 = \{\vec{\Omega}(t) \mid \vec{\Omega}'(t) \in L_1(0, T), \vec{\Omega}(0) = 0\}$.

Theorem 5. If $K_m(t)$ are summable functions, then system (5) has at least one solution $\vec{\Omega}(t) \in F_1$.

Remark. Since $F_1 \subset C(0, T)$, for continuous $K_m(t)$ it follows from equations (5) that $\vec{\Omega}'(t)$ is also continuous.

2. The nonstationary Navier–Stokes system. Let $Q = G \times [0, T]$, $G \subset \mathbf{R}^n$, $S = \partial G \times [0, T]$;

$$u' - \Delta u + \sum_{k=1}^n u_k \frac{\partial u}{\partial x_k} + \text{grad } p = h(x, t), \quad \text{div } u = 0, \quad (6)$$

$$u(x, 0) = 0, \quad u|_S = 0. \quad (7)$$

Put $X = \{u(x) \mid u \in \dot{W}_2^{(2)}(G), \text{div } u = 0\}$, $V = \{u(x) \mid u \in \dot{W}_q^{(1)}, q > n, \text{div } u = 0\}$; $p = 2$; $Y = L_1(Q)$, $A(u) = -\Delta u$, $B(u) = \sum_{k=1}^n u_k \frac{\partial u}{\partial x_k}$. Then

$$F_2 = \{u(x, t) \mid u \in L_2(\dot{W}_2^{(1)}), u' \in L_1(W_q^{(-1)}), u(x, 0) = 0\}.$$

Theorem 6. If $h(x, t) \in L_2(X^*)$, then system (6), (7) has at least one solution in F_2 .

This theorem refines the theorem of E. Hopf (9) (see also (8)); in particular, the finiteness of u' in $L_1(W_q^{(-1)})$ ensures the continuity of $u(x, t)$ in t in the sense of the space F_2 .

3. Analogy with example 2 of § 2. Consider in the cylinder $Q = G \times [0, T]$, $G \in \mathbf{R}^{2n}$, the first boundary-value problem for the system

$$\begin{aligned} \xi' + \Delta^2 \xi - \sum_{i=1}^n b_1^i(\xi, \chi) &= P_1(x_1, y_1, \dots, x_n, y_n, t), \\ \chi' + \Delta^2 \chi - \sum_{i=1}^n b_2^i(\xi) &= P_2(x_1, y_1, \dots, x_n, y_n, t), \end{aligned} \quad (8)$$

where $b_1^i(\xi, \chi)$, $b_2^i(\xi)$ are the same as in § 2, with (x, y) replaced by (x_i, y_i) .

Putting $X = \dot{W}_2^{(2)}(G)$, $V = \dot{W}_p^{(2)}$, $p > n/2$, $Y = L_1(Q)$, we obtain:

Theorem 7. If $P_i(\dots) \in L_2(W_2^{(-2)})$, $i = 1, 2$, then system (8) is solvable in the space $F_2 = \{u = (\xi, \chi) \mid u \in L_2(\dot{W}_2^{(2)}), u' \in L_1(W_p^{(-2)}), u(0) = 0\}$.
