CLASSES OF WELL-POSED SOLVABILITY OF A BOUNDARY-VALUE PROBLEM IN AN INFINITE LAYER

(Presented by Academician I. G. Petrovskii, 25 IV 1968)

We shall consider equations of the form

$$\partial^2 u(x, t) / \partial t^2 + P(\partial / \partial x) \partial u(x, t) / \partial t + Q(\partial / \partial x) u(x, t) = 0, \quad (1)$$

$$0 < t < T, \quad x = (x_1, \dots, x_n), \quad -\infty < x_i < \infty, \quad i = 1, \dots, n,$$

with boundary conditions

$$u(x, 0) = u_0(x), \quad u(x, T) = u_T(x), \quad -\infty < x_i < \infty, \quad i = 1, \dots, n. \quad (2)$$

Here $P(\partial / \partial x), Q(\partial / \partial x)$ are polynomials in $\partial / \partial x_1, \dots, \partial / \partial x_n$ with constant coefficients; $u_0(x), u_T(x)$ are prescribed functions. By a solution of problem (1)–(2) we shall mean (continuous) functions $u(x, t)$ satisfying equation (1) and conditions (2) in the sense of generalized functions (¹, pp. 129–130). We investigate the question: under what conditions on the smoothness, as well as on the growth as $|x| \rightarrow \infty$, of the functions $u_0(x)$ and $u_T(x)$ and their derivatives does a solution of problem (1)–(2) (in the above sense) exist and is unique* in one or another class of functions, and also depend continuously on the functions $u_0(x)$ and $u_T(x)$ in a sense that will be specified each time.

1°. **Definition 1.** Problem (1)–(2) is called **well-posedly solvable in the class of bounded functions** if:

- a) for any $l \geq 0$ there exists an $l_1 \geq 0$ such that, for any functions $u_0(x)$ and $u_T(x)$ bounded for all $x \in R_n$ together with all their derivatives up to order l_1 , there exists a unique solution $u(x, t)$ of problem (1)–(2), which for each $t \in (0, T)$ is bounded together with all its derivatives up to order l ;
- b) if the functions $u_{0m}(x)$ and $u_{Tm}(x)$ and their derivatives up to order l_1 tend (uniformly in R_n) to zero as $m \rightarrow \infty$, then the corresponding solutions $u_m(x, t)$

of problem (1)–(2), for each $t \in (0, T)$, also tend uniformly to zero together with their derivatives up to order l .

Introduce the following notation. Let Z be the set of those points $s = \sigma + i\tau = (\sigma_1 + i\tau_1, \dots, \sigma_n + i\tau_n)$ for which

$$D(s) \equiv \frac{1}{4}P^2(-is) - Q(-is) = -k^2\pi^2/T^2$$

for some integer $k \geq 1$. Denote

$$\Lambda(s) = |\operatorname{Re} P(is)| - 2|\operatorname{Re} \sqrt{D(-s)}|.$$

Definition 2. Equation (1) will be called **correct** if:

- a) real values $s = \sigma$ do not belong to the set Z ;
- b) the function $\Lambda(s)$ is bounded above for all real $s = \sigma$: $\Lambda(\sigma) \leq C$, $-\infty < \sigma_i < \infty$, $i = 1, \dots, n$. For example, any equation (1) for which $P(s) \equiv 0$ (or $P(s) \equiv \text{const}$) will be correct if condition a) is fulfilled for it. Thus the equations

$$\partial^2 u / \partial t^2 - \partial^2 u / \partial x^2 + \partial u / \partial x = 0, \quad \partial^2 u / \partial t^2 + \partial^2 u / \partial x^2 = 0,$$

$$\partial^2 u / \partial t^2 \pm \partial u / \partial x = 0 \tag{1'}$$

* The question of uniqueness of the solution of problem (1)–(2) is the subject of the author's note ⁽²⁾.

are correct, while the equation $\partial^2 u / \partial t^2 - \partial^2 u / \partial x^2 = 0$ is not correct.

The naturalness of singling out the class of correct equations is shown by the following

Theorem 1. *In order that problem (1)–(2) be correctly solvable in the class of bounded functions, it is necessary and sufficient that equation (1) be correct.*

2°. One can also indicate broader classes of functions (in the sense of growth at infinity) in which problem (1)–(2) for a correct equation (1) is correctly solvable.

Lemma 1. *If equation (1) is correct, then there exist constants $A > 0$ and α such that in the domain $\Delta_{\alpha, A}$*

$$\Delta_{\alpha, A} = \{s = \sigma + i\tau : |\tau| \leq A(1 + |\sigma|)^\alpha, -\infty < \sigma_i < \infty, i = 1, \dots, n\} \tag{3}$$

two conditions are satisfied: 1) $\Delta_{\alpha, A} \cap Z = \emptyset$; 2) there exists C_1 such that $\Lambda(s) \leq C_1$ for $s \in \Delta_{\alpha, A}$.

Definition 3. We shall call a correct equation (1) an **equation of zero type** if the result of Lemma 3 holds with $\alpha \geq 0$, and an **equation of negative type** otherwise. We shall say that a correct equation of negative type has type α_0 (< 0), if α_0 is the exact upper bound of those values of α for which the result of Lemma 1 is valid in $\Delta_{\alpha,A}$.

Denote by $M_{\beta,B}$ the class of (locally integrable) functions $f(x)$ satisfying the estimate

$$|f(x)| \leq C_f \exp\{B|x|^\beta\}. \quad (4)$$

Theorem 2. Let (1) be a correct equation of zero type, and let $A_0 > 0$ be the exact upper bound of those A for which, in the domain $\Delta_{0,A}$, the result of Lemma 1 is valid. Then for any $l \geq 0$ one can indicate an $l_1 \geq 0$ such that, for any functions $u_0(x)$, $u_T(x)$ which belong to the class $M_{1,B}$ ($B < A_0$) together with all their derivatives up to order l_1 , there exists in the class $M_{1,B}$ a unique solution $u(x,t)$ of problem (1)–(2); this solution has derivatives up to order l (with respect to x) belonging to $M_{1,B}$ and depends continuously on the functions $u_0(x)$, $u_T(x)$ in the following sense: if in the estimate

$$\max_{k \leq l_1} \max \left\{ \left| \partial^k u_{0m}(x) / \partial x_1^{k_1} \dots \partial x_n^{k_n} \right|, \left| \partial^k u_{Tm}(x) / \partial x_1^{k_1} \dots \partial x_n^{k_n} \right| \right\} \leq C_m \exp\{B|x|\},$$

$$m = 1, 2, \dots,$$

$C_m \rightarrow 0$ as $m \rightarrow \infty$, then in the corresponding estimate of the solution and its derivatives

$$\max_{k \leq l} |D^{(k)} u_m(x, t)| \leq C_{mt} \exp\{B|x|\}, \quad t \in (0, T),$$

also $C_{mt} \rightarrow 0$ as $m \rightarrow \infty$.

For example, the first of equations (1') is a correct equation of zero type. For it $A_0 = 1/2$, if $T \geq 2\pi$, and $A_0 = 1/2 - \sqrt{1/4 - \pi^2/T^2}$, if $0 < T \leq 2\pi$.

Theorem 3. Let (1) be a correct equation of negative type. Then for any $l \geq 0$ and $m \geq 0$ there exists an $l_1 \geq 0$ such that if the functions $u_0(x)$, $u_T(x)$ have polynomial order of growth m together with all their derivatives up to order l_1 :

$$\max_{k \leq l} \max \{ |D^{(k)} u_0(x)|, |D^{(k)} u_T(x)| \} \leq C(1 + |x|)^m, \quad (5)$$

then problem (1)–(2) has a (unique) solution $u(x,t)$, which together with its derivatives up to order l has polynomial order of growth not exceeding $m + n + 1$:

$$\max_{k \leq l} |D^{(k)}u(x, t)| \leq C_t(1 + |x|)^{m+n+1}, \quad 0 < t < T. \quad (6)$$

This solution depends continuously on the initial functions $u_0(x)$, $u_T(x)$ in the sense that C_t in (6) depends on C in (5) and tends to zero as $C \rightarrow 0$.

3°. **Definition 4.** We shall call the correct equation (1) **strongly correct** if there exist constants $C_1 > 0$, $h > 0$, and C_2 such that

$$\Lambda(\sigma) \leq -C_1|\sigma|^h + C_2, \quad -\infty < \sigma_i < \infty, \quad i = 1, \dots, n. \quad (7)$$

For example, the last two of equations (1') are strongly correct; for the first of them $h = 1$, for the second $h = \frac{1}{2}$.

For strongly correct equations there is a result analogous to that formulated in Lemma 1.

Lemma 2. There exists a domain $\Delta_{\alpha, A}$ of the form (3) such that $\Delta_{\alpha, A} \cap Z = \emptyset$, and in $\Delta_{\alpha, A}$ the estimate (7) is preserved, possibly with C_1 and C_2 replaced by some other constants $\hat{C}_1 > 0$ and $\hat{C}_2 > 0$, and h by any $h_1 < h$.

This fact makes it possible, analogously to Definition 3, to introduce a classification of strongly correct equations, distinguishing equations of zero kind and equations of negative kind α_0 .

Definition 5. We shall say that the problem (1)–(2) is **correctly solvable in the class of functions** $M_{\beta, B}$ if: 1) for any functions $u_0(x) \in M_{\beta, B}$ and $u_T(x) \in M_{\beta, B}$ there exists a unique solution $u(x, t)$ of problem (1)–(2), which for each $t \in (0, T)$ is a function of the class $M_{\beta, B}$; 2) if

$$|u_{0m}(x)| \leq C_m \exp\{B|x|^\beta\}, \quad |u_{Tm}(x)| \leq C_m \exp\{B|x|^\beta\}$$

and $C_m \rightarrow 0$ as $m \rightarrow \infty$, then the corresponding solutions $u_m(x, t)$ of problem (1)–(2) satisfy the estimates

$$|u_m(x, t)| \leq C_{tm} \exp\{B|x|^\beta\},$$

where $C_{tm} \rightarrow 0$ as $m \rightarrow \infty$ ($0 < t < T$).

Theorem 4. Let (1) be a strongly correct equation of zero kind, and let $A_0 > 0$ be the exact upper bound of those A for which, in the domain $\Delta_{0, A}$, the result of Lemma 2 is valid. Then the problem (1)–(2) is correctly solvable in any class $M_{1, B}$, where $B < A_0$, and also in any class $M_{\beta, B}$, where $0 < \beta < 1$, $B > 0$ is arbitrary.

For example, the second and third equations in (1) belong to the class of strongly correct equations of zero kind. For the first of them $A_0 = \pi/T$, for the second $A_0 = \pi^2/T^2$.

Theorem 5. Let equation (1) be a strongly correct equation of negative kind α . Then the problem (1)–(2) is correctly solvable in the class of functions $M_{\beta,B}$ for $\beta < h/(h - \alpha)$ and any $B > 0$.

4°. Theorems 4 and 5 show that correct solvability of the problem (1)–(2) for strongly correct equations takes place in classes of increasing functions without assumptions concerning the smoothness of the functions $u_0(x)$ and $u_T(x)$. It can be shown that in this case the solution of the problem (1)–(2) turns out to be an (infinitely) differentiable (with respect to x) function for $t \in (0, T)$. This property proves to be characteristic for strongly correct equations. Namely, the following holds.

Theorem 6. If, with respect to an equation of the form (1) (for $n = 1$), it is known that: a) the problem (1)–(2) for it is correctly solvable in some class of functions M , containing all bounded functions of the first Baire class, i.e., for any $u_0(x) \in M$ and $u_T(x) \in M$ there exists one and only one solution $u(x, t) \in M$, and from the fact that the sequences

$$u_{0m}(x) \rightarrow 0, \quad u_{Tm}(x) \rightarrow 0 \quad (m \rightarrow \infty)$$

uniformly on any interval and bounded on the whole line, it follows that the corresponding sequence of solutions

$$u_m(x, t) \rightarrow 0$$

in the same sense; b) the solution $u(x, t)$ of the problem (1)–(2) for any $t > 0$ is a continuously differentiable function, then equation (1) is strongly correct.

5°. We now single out those correct equations for which correct solvability of the problem (1)–(2) takes place in the class of all sufficiently smooth functions without restriction on their growth as $|x| \rightarrow \infty$.

Theorem 7. In order that problem (1)–(2) have a unique solution $u(x, t)$ for arbitrary functions $u_0(x)$ and $u_T(x)$ possessing derivatives up to some order l , and that from the fact that the sequences of functions $u_{0m}(x)$, $u_{Tm}(x)$ tend to zero as $m \rightarrow \infty$, together with all their derivatives up to order l , uniformly in every bounded domain, it should follow that the corresponding sequence of solutions $u_m(x, t)$, for each $t \in (0, T)$, also tends uniformly to zero in every bounded domain as $m \rightarrow \infty$, it is necessary and sufficient that equation (1) have the form

$$\left(\frac{\partial}{\partial t} + \sum_{k=1}^n A_k \frac{\partial}{\partial x_k} + B \right) \left(\frac{\partial}{\partial t} + \sum_{k=1}^n A_k \frac{\partial}{\partial x_k} + C \right) u(x, t) = 0,$$

where $A_1, \dots, A_n$ are arbitrary real constants, and B and C are complex constants, $T(B - C) \neq 2k\pi i$, $k = \pm 1, \pm 2, \dots$

Let us finally note that if equation (1) is not well-posed, then the existence of a solution of problem (1)–(2) can be guaranteed under the assumption that the

functions $u_0(x)$ and $u_T(x)$ are continued into the complex space $z = x + iy$ in such a way that entire functions of exponential type are obtained, depending on equation (1).
